Algorithm (Kosaraju's):

Key Properties:

end for u.color ← BLACK ▷ Finishing tim  $time \leftarrow time + 1$  $u, f \leftarrow \text{time}$ 24. and procedure

Compute the bottless pacity  $c_f(p)$  (the minimum 7. residual capacity along p). Augment flow f along p by 9:  $c_f(p)$ .

Residual Network: Given flow f define residual capacity  $c_f$  as:

 $c_f(u,v) = \begin{cases} c(u,v) - f(u,v) & \text{if } (u,v) \in E \\ f(v,u) & \text{if } (v,u) \in E \\ \text{otherwise} \end{cases}$  Then the residual graph is  $G_f = C_f(u,v)$ that for every edge  $(u, v) \in E$ , vertex  $(V, E_f)$  where  $E_f = \{(u, v) \in V \times V\}$  $V : c_f(u, v) > 0$ .

by performing DFS and order-Cuts and Optimality:

 $u, v \in V$ ,

edge (u, v).

 $V \setminus \{s, t\},\$ 

Algorithm:

 $(u, v) \in E$ .

source and sink).

 $0 \le f(u,v) \le c(u,v)$ 

Flow Conservation: For all u

 $v \in V \quad f(v, u) = v \in V \quad f(u, v)$ 

Value of the Flow:  $|f| = \int_{v \in V} f(s, v) - \int_{v \in V} f(v, s)$ 

This represents the total net flow out

The Ford-Fulkerson method finds the

sink t in a flow network G = (V, E)

Initialize flow f(u, v) = 0 for all

While there exists an augment

• Compute the **bottleneck ca-**

of the source s. Ford-Fulkerson Method (1954)

ing vertices in decreasing order of  $\bullet$  A cut (S,T) of the network is partition of V with  $s \in S$ ,  $t \in T$ The flow across the cut is:  $f(S,T) = \max_{u \in S} \sup_{v \in T} f(u,v) - \max_{u \in T, v \in S} f(u,v)$ 

 The capacity of the cut is:  $c(S,T) = u \in S, v \in T \ c(u,v)$ 

 For any flow f and any cut (S, T) we have:  $|f| \le c(S, T)$ .

Max-Flow Min-Cut Theorem: The value of the maximum flow equals the capacity of the minimum

V, E) is a maximal set of vertices Augmenting Path Is a path from  $C \subseteq V$  such that for every pair u,  $v \in \text{the source to the sink in the residual}$  C, there is a path from u to v and v and v and v the such that every edge on the path has available capacity from v to u.

Transpose of a Graph: The trans-Complexity: O(Ef) where f is max

pose of G, denoted  $G^T = (V, E^T)$ , flow Bipartite Graphs bipartite graph (or bigraph) is graph G = (U, V, E) whose vertices G and GT share the same SCCs can be partitioned into two disjoint sets U and V such that every edge Computing  $G^T$  takes  $\Theta(|V| + |E|)$ connects a vertex from U to one in

Properties:

Run DFS on G to compute finish-  $\hat{U}$  and V are called the parts of the graph.

 Bipartiteness can be tested using 10: BÉS:

Label the source s as even.
During BFS, label each unvis During BF5, label each univis- 13: return A ited neighbor of a vertex with 14: end procedure the opposite parity (even  $\leftrightarrow$  Runtime:  $\Theta(|E| \log |E|)$  due to sortodd).

is visited twice with the same parity), the graph is not bipar-

tite. Bipartite Match via Max-Flow

• 1. Add a source node s and connect it to all nodes in the left partition (say U) and do same for right part to sink.

2. For each edge (u, v) in the bipartite graph (with  $u \in U$ ,  $v \in$ V), add a directed edge from u to

• 3. Assign a capacity of 1 to all edges.

Run Ford-Fulkerson from

Bellman-Ford Algorithm Spanning Tree: A spanning tree T of

edge-disjoint s-t paths.

ing, plus nearly linear time for Unionand path compression). Edge Disjoint Paths using Max

ou can use the Max-Flow algorithm to find all edge-disjoint paths from a source to a sink by assigning a capac-

n a weighted graph G = (V, E), al owing negative edge weights. Key Idea:

· Relax all edges repeatedly (up to |V| = 1 times).

 After that, check for negative weight cycles: if we can still relax an edge, a negative cycle exists.

nitialization: procedure Init-Single-Source(G, s) for each  $v \in G.V$  do

 $v.d \leftarrow \infty$   $\triangleright$  distance estimate  $v.\pi \leftarrow \text{NIL}$   $\triangleright$  predecessed

procedure RELAX(u, v, w)if v.d > u.d + w(u,v) then  $v.d \leftarrow u.d + w(u, v)$ end if

Algorithm

```
Main
1. procedure Brilman-Ford (G w e)
      INIT-SINGLE-SOURCE (C .)
      for i \leftarrow 1 to |G|V| = 1 do
         for each edge (u, v) \in G.E do
          BELAX(u. v. w)
         end for
      for each edge (u, v) \in G.E.do
         if v, d > u, d + w(u, v) then
            return false > Negative-weigh
   cycle detected
         end if
       return true
 4: end procedure
Buntime: \Theta(|V||E|)
Handles: Negative weights (but no
 negative cycles)
Dijkstra's Algorithm
```

Goal: Compute the shortest paths rom a single source s to all other verices in a weighted graph G = (V, E)with non-negative edge weights. Kev Idea:

Greedily grow a set S of vertices 8.

with known shortest paths. At each step, pick the vertex u S with the smallest tentative dis-11.

tance u.d.Relax all edges (u, v) from u to undate distance estimates.

Pseudocode: 1: procedure DUKSTRA(G. w. s) INIT-SINGLE-SOURCE (G, s) $S \leftarrow \emptyset$  $Q \leftarrow G.V$  | insert all vertices int priority queue Qwhile  $Q \neq \emptyset$  do  $u \leftarrow \text{Extract-Min}(Q)$ 

 $S \leftarrow S \cup \{u\}$ for each  $v \in Adj[u]$  do Relax(u, v, w)end for end while

12: end procedure Runtime:  $\Theta(|E| \log |V|)$ 

ise a function h(k) mapping keys t ndices in the range 1 to p, such tha each element is stored at index h(k)Collisions are managed using chair ing (linked lists), leading to:

O(1) insertion

 O(N + E) search (in worst-case) O(1) deletion

Collisions in Hash Table odd). ing, plus nearly linear time for Union-For a table of size m, the probabilif a conflict arises (a vertex Find operations (with union by rank lity of a collision between two keys i, i $\frac{1}{m}$ . The probability of a specific k-way collision is  $\frac{1}{m^{k-1}}$ . The total Optimal stopping (skip r candidates).  $m^{n-1}$  number of pairwise collisions is:

 $\sum_{i=1}^{n-1} \sum_{j=i+1}^{n} \frac{1}{m} = \binom{n}{2} \cdot \frac{1}{m}$ ity of 1 to every edge and running i=1 j=i+1 m  $_{2}$   $_{m}$  Ford-Fulkerson. The maximum flow More generally, the expected number Ford-Fulkerson. The maximum nownword of k-collisions is:

 $\underbrace{1 \leq i_1 < \dots < i_k \leq n} \frac{1}{m^{k-1}} = 1$ 

The Hiring Problem We interview n candidates for a position, one by one in ran-input piece-by-piece in a serial fash decide immediately whether to hire the candidate. We want to compute it must make decisions based only on the expected number of times we hire the current and past inputs without someone (i.e., when they are better knowledge of future inputs. han all previous candidates).

Indicator Random Variable: Given a sample space and an event A, the indicator random variable fo A is defined as:  $I\{A\} = \begin{vmatrix} 1 & \text{if } A \text{ occurs,} \\ 0 & \text{if } A \text{ does not occur.} \end{vmatrix}$ 

Then:

 $[I\{A\}] = P(A)$ Expected Number of Hires: Let X be the total number of hires. Define  $X = \underset{i=1}{n} I_i$ , where  $I_i = 1$  if the *i*-th candidate is hired (i.e., better than all previous i-1), and 0 otherwise.

 $[X] = {n \atop i=1} [I_i] = {n \atop i=1} {1 \over i} = H_n$ Conclusion: The expected number

of hires is  $\Theta(\log n)$ , even though there are n candidates. Quick Sort

lgorithm with the following steps:

Divide: Partition  $A[p, \ldots, r]$ into two (possibly empty) subarrays  $A[p, \ldots, q-1]$  and A[q+1]1....r such that each element in the first subarray is  $\leq A[q]$  and **Setup**:

two subarrays by calling Quick Sort on them.
Combine: No work is needed t combine the subarrays since th

sorting is done in-place.

procedure Partition(A, p, r) $x \leftarrow A[r]$  $i \leftarrow p - 1$ for  $i \leftarrow p$  to r - 1 do if  $A[j] \leq x$  then exchange A[i] with A[j]and if end for exchange A[i+1] with A[r]return  $i \perp 1$ 

2: end procedure 1: procedure QUICK-SORT(A, p, r) if v < r then  $q \leftarrow Partition(A, p, r)$ 

Quick-Sort (A, p, q - 1)Quick-Sort (A, q + 1, r)

end procedure 1: procedure RANDOMIZED-PARTITION(A, p, r)  $i \leftarrow \text{Random}(p, r)$ exchange A[r] with A[i]4: return Partition(A, p, r)

5. and procedure 1: procedure Randomized-Quick-Sort(A, p, r) if n < r then

 $a \leftarrow \text{Randomized-Partition}(A, n, r)$ Quick-Sort (A, p, q - 1)Quick-Sort (A, a + 1, r)end if

end procedure Random Runtime:  $\Theta(|N| \log |N|)$ Worst Runtime:  $\Theta(|N|^2)$ Hiring Problem

so far. The first candidate is alway hired. Candidate i is hired if no bet er candidate appeared before:

 $\Pr[\text{hire } i] = \stackrel{\cdot}{-} \Rightarrow [\text{total hires}] =$ 

dates): To maximize chance of hiring Use cases: Adversarial learning

Pr[hire best] =  $\frac{1}{n} \frac{n}{i=r+1} \frac{r}{i-1}$  $\approx \frac{r}{r} \ln |\underline{n}|$  Maximized when  $r \approx n/r$ 

Online Algorithms An online algorithm processe on, i.e., it does not have access to the entire input from the start. Instead Characteristics:

Decisions are made in real-time. Decisions are made in real-ville.
 Cannot revise past decisions once new input arrives.

Often evaluated using competitive analysis, comparing performance to an optimal offline algorithm.

Competitive Ratio: If  $\bar{C}_{\mathrm{online}}$ the cost incurred by the online algorithm and  $C_{
m opt}$  is the cost incurred by an optimal offline algorithm, then the competitive ratio is defined as:

 $\begin{array}{|c|c|c|c|c|c|} \hline \text{Competitive Ratio} = \max_{\text{input}} \frac{c_{\text{online}}}{C_{\text{opt}}} \end{array}$ 

An algorithm is said to be r competitive if this ratio is at most

Weighted Majority Algorithm The Weighted Majority Algorithm (WMA) is an online learning algorithm that maintains a set of "experts" (prediction strategies), each assigned a weight. The algorithm predicts based on a weighted vote of the experts and penalizes those who

make incorrect predictions. each element in the second subar- • n experts, each with an initial

weight  $w : \leftarrow 1$ . Conquer: Recursively sort the  $\bullet$  At each time step t, each expert makes a prediction.

. The algorithm makes its own prediction based on a weighted ma jority.

 After the outcome is revealed, ex perts that predicted incorrectly are penalized by multiplying their weight by a factor  $\beta \in (0, 1)$ .

Guarantees: If there is an exper that makes at most m mistakes, then the number of mistakes made by the algorithm is at most:

 $M < (1 + \log n) \cdot m$ (up to constant factors depending on

Use cases: Binary prediction probems, stock forecasting, game play

Hedge Algorithm he **Hedge Algorithm** generalize Weighted Majority to handle realvalued losses and probabilistic pre dictions. It is used in adversarial multi-armed bandit and online optimization settings.

Setup: n actions (or experts), each with weight  $w_i^{(t)}$  at round t.

 At each time step, the algorithm picks a probability distribution p(t) over actions, where:

$$p_i^{(t)} = \frac{w_i^{(t)}}{j \ w_j^{(t)}}$$

• After observing losses  $\ell_{:}^{(t)}$ [0, 1], weights are updated as:  $w_i^{(t+1)} = w_i^{(t)} \cdot e^{-\eta \ell_i^{(t)}}$ 

where  $\eta > 0$  is the learning rate. Guarantees: For any expert i, the regret after T rounds is bounded by:

Regret 
$$\leq \eta T + \frac{\log n}{n}$$

Setting  $\eta = \frac{\log n}{n}$  gives regret of or  $\operatorname{der} O(\sqrt{T \log n})$
